

# Naming Compounds Class Notes

OBJECTIVE : What are ions, how do they form, why do they form, what happens once they form?

1. All atoms are neutral because they have \_\_\_\_\_

2. \_\_\_\_\_, so that's okay.

To start, Noble gases never make any bonds because they are "perfect" (think noble) Remember in story books how noblemen or noblewomen could never marry a peasant? Same here.

3. Noble Gases Do Not Make Bonds because they are "\_\_\_\_\_!"

Which really means they have only FULL \_\_\_\_\_

They feel fine just the way they are.

4. All other atoms have their outer-most electron orbitals \_\_\_\_\_

5. Giving up negative electrons changes them into charged particles called IONS. Metal ions \_\_\_\_\_ electrons, only electrons, so they end up + charged.

If a metal loses 1 electron they form +1 ions. If they lose 2 electrons they become +2 charged ions. If they lose 3 electrons they become +3 ions.

6. To make bonds, metal atoms lose enough electrons to become \_\_\_\_\_ with a noble gas. That means they lose only enough electrons to match electron configurations.

7. They \_\_\_\_\_ BECOME noble gases! (write this BIG!)

8. Noble gases are "noble" because they have completely \_\_\_\_\_

"Noble like means won't bond, like the nobles of thrones and castles don't mix with the peasants. Noble gases don't bond to peasant elements either. Noble gases are all in GROUP \_\_\_\_\_

9. Noble gases do not bond because they don't need to share their electrons with other atoms to "get" full orbitals. They don't want to lose electrons or gain any either. They're "\_\_\_\_\_ " already.

Since electrons are negatively charged, it becomes a \_\_\_\_\_

10. Let's Look at our "standard atom" sodium. How many electrons does sodium need to "lose" to get a noble gas configuration? Hint: Look at Neon on the periodic table.
11. Na 2-8-1 will \_\_\_\_\_, which will give it an electron configuration of 2-8
12. This 2-8 is the same electron configuration as \_\_\_\_\_. Which is just like neon, a noble gas. Since  $e^-$  are negatively charged, it becomes a sodium +1 ion.
14. The sodium + ion, with \_\_\_\_\_  $p^+$ , but only \_\_\_\_\_  $e^-$ , which gives it an over all charge of \_\_\_\_\_  
It is written like this:
15. Metal atoms will lose one, two or three electrons to get the same electron configuration as a noble gas. They will form positive ions with charges of: \_\_\_\_\_ or \_\_\_\_\_ or \_\_\_\_\_  
Depending if they lose one, two, or three electrons.
16. Nonmetal atoms will do the opposite. They must gain \_\_\_\_\_ electrons to be \_\_\_\_\_ with a noble gas. They will end up with a \_\_\_\_\_ or \_\_\_\_\_ or \_\_\_\_\_  
Depending if they gain 1, 2 or 3 electrons.
17. Ions form when a metal can lose electrons and give them to a non metal that can gain the same electrons.  
Electrons are NOT LOST really, they are \_\_\_\_\_ from a metal to a nonmetal at the same time. Positive and negative ions only form simultaneously.
18. Ions do not have to form, but in order for a metal and a nonmetal to bond together, there needs to be a transfer of electrons that is PERFECT, so that the metal ends up \_\_\_\_\_, and the nonmetal ends up \_\_\_\_\_
19. The noble gases in \_\_\_\_\_ are sort of the electron configuration "models" for other atoms to match in order for bonding to occur.
20. Bonds between metal and nonmetal ions are called \_\_\_\_\_ and they are the strongest bonds in chemistry

Atom	Atom e <sup>-</sup> config	Ion e <sup>-</sup> config	Ion symbol
Li	2-1		
Na	2-8-1		
K	2-8-8-1		
Rb	2-8-18-8-1		
Be	2-2		
Mg	2-8-2		
Ca	2-8-8-2		
Al	2-8-3		

21. All metals LOSE electrons to become positive ions. POSITIVE IONS are called \_\_\_\_\_.
22. They give up their neutrality for a \_\_\_\_\_ charge, but get that \_\_\_\_\_ e<sup>-</sup> configuration.
23. Non metals become \_\_\_\_\_ which are negative ions, because they gain negative electrons

Atom	Atom e <sup>-</sup> config	Anion e <sup>-</sup> config	Ion symbol
F	2-7		
Cl	2-8-7		
Br	2-8-18-7		
I	2-8-18-18-7		
O	2-6		
S	2-8-6		
N	2-5		
P	2-8-5		

23b. Metals lose electrons becoming, or forming into \_\_\_\_\_ cations.

23c. Nonmetals gain those electrons from metals, so they become, or form into \_\_\_\_\_ anions.

23d. Cations + anions will bond together with \_\_\_\_\_

The attraction between the positive + negative ions is \_\_\_\_\_.

23e. The bonding requires \_\_\_\_\_ of positive and negative charges.

For example sodium chloride, NaCl requires 1 Na<sup>+1</sup> cation for every Cl<sup>-1</sup> anion to form.

The positive charge = the negative charge in the compound.

Magnesium oxide forms when the \_\_\_\_\_ cation and the \_\_\_\_\_ anion form together.

This is also a 1:1 ratio of cations to anions, keeping the \_\_\_\_\_ = \_\_\_\_\_ here too.

Naming Compounds Class #2

24. OB: \_\_\_\_\_

25. Ionic compounds form when \_\_\_\_\_ (metals) come together with \_\_\_\_\_  
(non-metals) and are \_\_\_\_\_ attracted due to opposite charge.

26. Cations form when metals \_\_\_\_\_ electrons to nonmetals, which simultaneously form - anions.

27. Opposites attract, it's like \_\_\_\_\_!!!

28. There is ALWAYS a \_\_\_\_\_ of electrons, and if not, nothing happens.

29. There are 2 rules to name ionic compounds: the 1st name rule, and the 2nd name rule

30. 1<sup>st</sup> name rule: \_\_\_\_\_

31. 2<sup>nd</sup> name rule: \_\_\_\_\_

32. F \_\_\_\_\_ Cl \_\_\_\_\_ Br \_\_\_\_\_

I \_\_\_\_\_ O \_\_\_\_\_ S \_\_\_\_\_

(Se) \_\_\_\_\_ N \_\_\_\_\_ P \_\_\_\_\_

and (As) \_\_\_\_\_

33. Name these compounds: LiBr \_\_\_\_\_ CaO \_\_\_\_\_

BeS \_\_\_\_\_ MgO \_\_\_\_\_

CsF \_\_\_\_\_ SrS \_\_\_\_\_

AlP \_\_\_\_\_

35. What happens if we combine something like calcium and chlorine?

$\text{Ca}^{+2}$  ion forms when calcium atoms lose \_\_\_\_\_ electrons

Combine it with a Chloride ion, which forms when a chlorine atom \_\_\_\_\_ electron.  
2 electrons transfer from calcium do not match up to 1 electron gain by chlorine??

36.  $\text{Ca}^{+2} + \text{Cl}^{-1}$  \_\_\_\_\_ a \_\_\_\_\_ ratio

37. The  $\text{Ca}^{+2}$  must transfer \_\_\_\_\_ to \_\_\_\_\_ chlorine atoms,  
forming 2 chloride anions.

38. Calcium chloride is therefore written this way: \_\_\_\_\_

39. Cation	Anion	Formula of compound	Name of compound
$\text{Na}^{+1}$	$\text{P}^{-3}$		
$\text{Ca}^{+2}$	$\text{S}^{-2}$		
$\text{Al}^{+3}$	$\text{P}^{-3}$		
$\text{Mg}^{+2}$	$\text{Br}^{-1}$		
$\text{Li}^{+1}$	$\text{O}^{-2}$		

40. Cation	Anion	Formula of compound	Name of compound
$\text{Be}^{+2}$	$\text{F}^{-1}$		
$\text{Sr}^{+2}$	$\text{Cl}^{-1}$		
$\text{Ba}^{+2}$	$\text{N}^{-3}$		
$\text{K}^{+1}$	$\text{I}^{-1}$		
$\text{Al}^{+3}$	$\text{O}^{-2}$		

41. Criss-Cross Method of nonthinking, but getting it right What's the formula for aluminium oxide?

42. Name these compounds (aloud and write their names too)

LiCl \_\_\_\_\_

CsF \_\_\_\_\_

BeO \_\_\_\_\_

MgS \_\_\_\_\_

MgF<sub>2</sub> \_\_\_\_\_

Ca<sub>3</sub>P<sub>2</sub> \_\_\_\_\_

Li<sub>3</sub>P \_\_\_\_\_

Na<sub>3</sub>N \_\_\_\_\_

Al<sub>2</sub>O<sub>3</sub> \_\_\_\_\_

43. The compounds formed when ions bond together are called \_\_\_\_\_ Compounds

44. They have \_\_\_\_\_ bonds holding them together, so,

they have \_\_\_\_\_ points, and \_\_\_\_\_ BP's.

45. Ionic compounds only form when

\_\_\_\_\_.

"perfectly". No loose electrons, and NO IOU electrons either!

OB: Transitional Metals become ions too.

The rules for ionic bonding and naming ionic compounds from the middle of the table.

46. Group 1 all make only \_\_\_\_\_, because all \_\_\_\_\_ 1 electron in the outer orbital
47. Group 2 all make \_\_\_\_\_, because they all \_\_\_\_\_ from their outer orbital
48. Aluminum makes a \_\_\_\_\_, because it would \_\_\_\_\_ when it forms a cation
49. Group 17 atoms all make \_\_\_\_\_, because they \_\_\_\_\_ to become  
\_\_\_\_\_ (get same electron configuration as a noble gas).
50. Group 16 all make \_\_\_\_\_, they need to \_\_\_\_\_ to fill their outer orbital
51. Group 15 atoms become \_\_\_\_\_
52. Scandium makes a \_\_\_\_\_. See that +3 in the corner? That's what it's for.
53. Yttrium too, makes a \_\_\_\_\_. Peek at zinc, it only makes a \_\_\_\_\_.
54. The transitional metals make the cations that are indicated, they \_\_\_\_\_,  
\_\_\_\_\_ like metals we've seen in groups 1 and 2 and Aluminum.
55. When the transitional metals form cations and bond to anions they make \_\_\_\_\_.  
Naming these compounds works the same way as the ones you have already met.
56. React these atoms of scandium and chlorine by changing them to ions, write formulas and names...

Sc + Cl \_\_\_\_\_ name: \_\_\_\_\_

Combine these atoms together into ionic compounds Show ion charges, and formula and name the compound

57. Zr and P \_\_\_\_\_ stock name: \_\_\_\_\_

58. In and F \_\_\_\_\_ stock name: \_\_\_\_\_

59. Titanium is our first special case. What ions does Titanium seem to make? \_\_\_\_\_ and \_\_\_\_\_

60. From this list of transitional metals, list all the ions each can form into

Cr-24 \_\_\_\_\_ Fe-26 \_\_\_\_\_ Cu-29 \_\_\_\_\_

Ga-31 \_\_\_\_\_ Cd-48 \_\_\_\_\_ Nb-41 \_\_\_\_\_

Hg-80 \_\_\_\_\_

61. Combine gold with chlorine (do both cations, one at a time) Write the formulas. And Names.

Au + Cl  $Au^{+1} + Cl^{-1}$  \_\_\_\_\_ stock name: \_\_\_\_\_

Au + Cl  $Au^{+3} + Cl^{-1}$  \_\_\_\_\_ stock name: \_\_\_\_\_

62. Combine all manganese cations with bromine. Write ions, formulas and stock names for each one.

Mn + Br \_\_\_\_\_ stock name: \_\_\_\_\_

Mn + Br \_\_\_\_\_ stock name: \_\_\_\_\_

Mn + Br \_\_\_\_\_ stock name: \_\_\_\_\_

Mn + Br \_\_\_\_\_ stock name: \_\_\_\_\_

63. Do the same for the two kinds of copper ions as they combine with oxygen (we saw them in lab, black + red)

Cu + O \_\_\_\_\_ stock name: \_\_\_\_\_

Cu + O \_\_\_\_\_ stock name: \_\_\_\_\_

64. Combine Tantalum and Sulfur now, show ions and formula, and the stock name

Ta + S \_\_\_\_\_ stock name: \_\_\_\_\_

65. Tricked you (didn't I?) write proper name for NaCl and then write the WRONG name to remind you how to think about transitional metal ionic compounds and their roman numerals.

NaCl \_\_\_\_\_ stock name: \_\_\_\_\_

WRONG name \_\_\_\_\_ why is it wrong? \_\_\_\_\_

Naming Compounds Class #4 OBJECTIVE: Table E, the polyatomic ions, making more ionic compounds!

66. Table E shows us the \_\_\_\_\_.  
Poly means more than one, here, atomic means atoms that are stuck together.

POLYATOMIC IONS are 2 or more atoms bonded together in certain ways that act as a single ion (positive cations, or negative anions). All are on table E. Let's read the names now, bottom to top.

67. They have special names, and you never ever change their names. Most end in -ide, like good little anions, but some don't. Why? \_\_\_\_\_

68. We'll start talking about ammonium.

Ammonium is \_\_\_\_\_ atom bonded with \_\_\_\_\_ atoms,

but they act as a +1 cation (like  $\text{Na}^{+1}$  or  $\text{Li}^{+1}$ ). They just come hand cuffed (bonded) together.

69. Working with the polyatomic ions, remember these rules:

\_\_\_\_\_ still go first, always. \_\_\_\_\_ still always go second.

\_\_\_\_\_ a table E polyatomic ion.

70. Let's try to bond (name then formula)

$\text{Na}^{+1}$  and  $\text{C}_2\text{H}_3\text{O}_2^{-1}$  will form \_\_\_\_\_

$\text{K}^{+1}$  and  $\text{CN}^{-1}$  will form into \_\_\_\_\_

71. These are really easy, except when the polyatomics have to \_\_\_\_\_, like these:

Magnesium cation + hydroxide ion forms magnesium hydroxide

Write the ion formulas \_\_\_\_\_ How many Magnesium ions do we need? \_\_\_\_\_

How many Hydroxide ions do we need? \_\_\_\_\_ (get them)

72. The formula for magnesium hydroxide is \_\_\_\_\_ (the parenthesis show \_\_\_\_\_)

73. Combine (show ions, show formulas, name stock names):

Lithium + the chromate anion \_\_\_\_\_ stock name: \_\_\_\_\_

Aluminum + hypochlorite anion \_\_\_\_\_ stock name: \_\_\_\_\_

Magnesium + thiocyanate anion \_\_\_\_\_ stock name: \_\_\_\_\_

Calcium + permanganate anion \_\_\_\_\_ stock name: \_\_\_\_\_

74. Try a few more formula from names:

What is the formula for beryllium phosphate? \_\_\_\_\_

What's the formula for sodium hydrogen carbonate? \_\_\_\_\_

ammonium nitrate? \_\_\_\_\_

ammonium dichromate? \_\_\_\_\_

Bismuth (V) thiosulfate \_\_\_\_\_

Cobalt (III) chlorate \_\_\_\_\_

## Naming Compounds Class #5

OBJECTIVE: molecular compounds, naming and formulas, and determining how to form molecular compounds using selected oxidation states.

75. Ionic compounds form when \_\_\_\_\_ combine in proper ratio with \_\_\_\_\_, attracting to each other because of opposite charge.

\* except for that weird ammonium: \_\_\_\_\_.

76. With molecular compounds have \_\_\_\_\_.

Molecular compounds form when 2 or more nonmetals bond together—in proper ratios.

There are NO ions, no ionic bonds either.

77. When two or more non metals bond together they form a \_\_\_\_\_.

78. A molecule is the \_\_\_\_\_ of a molecular compound.

79. The bonds that hold these atoms together is called a \_\_\_\_\_ bond.

80. Co- means \_\_\_\_\_ -valent refers to the \_\_\_\_\_ or outermost \_\_\_\_\_.

81. When 2 or more ions bond, they make ionic bonds, and they form into \_\_\_\_\_.

We can abbreviate that \_\_\_\_\_.

82. NaCl \_\_\_\_\_ come in molecules, since it does not exist as a single particle.

It's a crystal, or dissolved in water. Ionic Compounds \_\_\_\_\_.

83. What 3 compounds to remember to KNOW how to name molecular compounds: \_\_\_\_\_

Names: \_\_\_\_\_

84. First Name Rule to name molecular compounds:

a single atom to start: \_\_\_\_\_

a multiple atom start: \_\_\_\_\_

85. Second Name Rule to name molecular compounds: \_\_\_\_\_

86. List the Latin Prefixes for 1 through 10, memorize these at your earliest convenience.

87. Using the 2 rules, and the Latin Prefixes, let's name these 10 example molecules.

HF \_\_\_\_\_

CS<sub>2</sub> \_\_\_\_\_

SO<sub>3</sub> \_\_\_\_\_

CCl<sub>4</sub> \_\_\_\_\_

PF<sub>5</sub> \_\_\_\_\_

SF<sub>6</sub> \_\_\_\_\_

Cl<sub>2</sub>O<sub>8</sub> \_\_\_\_\_

I<sub>4</sub>O<sub>9</sub> \_\_\_\_\_

N<sub>2</sub>F<sub>10</sub> \_\_\_\_\_

88. Write the formulas for each molecule:

Phosphorous tribromide \_\_\_\_\_

Diphosphorous trioxide \_\_\_\_\_

Oxygen difluoride \_\_\_\_\_

Dihydrogen monoxide \_\_\_\_\_

Nitrogen monoxide \_\_\_\_\_

89. Now in reverse, name these compounds

NO<sub>2</sub> \_\_\_\_\_

Cl<sub>4</sub> \_\_\_\_\_

N<sub>2</sub>O \_\_\_\_\_

SO<sub>3</sub> \_\_\_\_\_

N<sub>2</sub>O<sub>5</sub> \_\_\_\_\_

HCl \_\_\_\_\_

90. The 7 atoms on the periodic table that only exist AS PAIRS of ATOMS (a molecule) when pure include the

\_\_\_\_\_ twins, with these formulas: \_\_\_\_\_

91. How do we decide what ratios of nonmetal atoms fit together to make compounds? Why is water  $H_2O$  and NO OTHER hydrogen-oxygen compounds exist in any other ratio (like  $H_3O$  or  $H_4O_2$ )?

92. We will use the \_\_\_\_\_ from the periodic table to think.

93. Here's a chart:

We will use these oxidation numbers to figure out possible ratios that balance out to ZERO.

Only the ratios that balance to zero are possible compounds. No exceptions.

94. The only possible "Zero" balance ratio is \_\_\_\_\_. This is THE ONLY hydrogen/oxygen compound in our class. Sometimes other oxidation numbers exist, and other compounds can be made.

We are using "SELECTED" oxidation states, to let us practice and learn but NOT KNOW everything. It's okay.

95. Let's determine all of the possible carbon and oxygen compounds that could form with their selected oxidation states. (use the chart)

96. List names and formulas of ALL carbon/oxygen compounds in our course:

96. Let's do the big one: All Nitrogen + Oxygen Compounds (there are 5) Formulas and names
